

# **TUTORIAL 3 BASE CONVERSION AND INTEGER REPRESENTATION**

# Overview

---

- **We will review the following concept in this tutorial:**
- **Base conversion**
  - Between base 2 (binary) and base 10 (decimal)
  - Between base 2 (binary) and base 16 (hexadecimal)
- **Representation of integers**
  - Signed magnitude representation
  - One's complement
  - Two's complement

# The Decimal (Base 10) representation

- We are using the decimal (base 10) number system to represent numbers in our daily lives.
- For example when we say a year has  $365_{(10)}$  days, this decimal number  $365_{(10)}$  really means the following:

$$\begin{aligned} 365_{(10)} &= 300 + 60 + 5 \\ 365_{(10)} &= 3 \times 100 + 6 \times 10 + 5 \times 1 \\ 365_{(10)} &= 3 \times 10^2 + 6 \times 10^1 + 5 \times 10^0 \end{aligned}$$

- When we represent a fractional number in the decimal (base 10) format like in the following, it really means:

$$\begin{aligned} 365.25_{(10)} &= 3 \times 10^2 + 6 \times 10^1 + 5 \times 10^0 + 2 \times 10^{-1} \\ &\quad + 5 \times 10^{-2} \end{aligned}$$

# The General Base $r$ Representation

- In general we can represent a number using any *base* (or radix)  $r$ :

$$\underbrace{(a_n \dots a_5 a_4 a_3 a_2 a_1 a_0)}_{\text{Integer part}} \cdot \underbrace{a_{-1} a_{-2} a_{-3} a_{-4} \dots a_{-m}}_{\text{Fractional part}})_r \quad a_i < r$$

- For example: the following fractional number represented in base  $r$  is really:

$$(a_n \dots a_5 a_4 a_3 a_2 a_1 a_0 \cdot a_{-1} a_{-2} a_{-3} a_{-4} \dots a_{-m})_r$$

$$= a_n \times r^n + a_{n-1} \times r^{n-1} + a_{n-2} \times r^{n-2} + \dots + a_0 \times r^0 + a_{-1} \times r^{-1} + \dots + a_{-m} \times r^{-m}$$

# Warm up exercise 1

---

- Convert number from binary to decimal
- Q1.  $(111.01)_2 = (?)_{10}$

## Warm up exercise 2

---

- Convert number from decimal to binary
- Q2.  $(26)_{10} = (?)_2$

## Warm up exercise 3

---

- Convert number from decimal to hexadecimal
- Q3.  $(426)_{10} = (?)_{16}$

## Warm up exercise 4

---

- Convert number from binary to hexadecimal
- Q4.  $(11010110)_2 = (?)_{16}$

## Different notation of base 16

---

- They are all representing a same hexadecimal number

$$2BC_{16} = 2BC_{\text{hex}} = 0x2BC$$

## Extra exercises

---

- Convert  $37_{(10)}$  to the binary format.
- Convert  $1034_{(10)}$  to the binary format.
- Convert the positive integer  $101001_{(2)}$  to the decimal format.
- Convert  $10111001_{(2)}$  to the hexadecimal format.
- Convert  $A7_{(16)}$  to the binary format.

# Signed magnitude representation

- Humans use a **signed-magnitude** system: we add + or - in front of a magnitude to indicate the sign.
- We could do this in binary as well, by adding an extra sign bit to the front of our numbers.
  - A 0 sign bit represents a positive number.
  - A 1 sign bit represents a negative number.
- Examples:

$1101_2 = 13_{10}$  (a 4-bit unsigned number)  
 $01101 = +13_{10}$  (a positive number in 5-bit signed magnitude)  
 $11101 = -13_{10}$  (a negative number in 5-bit signed magnitude)

$0100_2 = 4_{10}$  (a 4-bit unsigned number)  
 $00100 = +4_{10}$  (a positive number in 5-bit signed magnitude)  
 $10100 = -4_{10}$  (a negative number in 5-bit signed magnitude)

# Arithmetic with signed magnitude

- Adding numbers is difficult, though. You can't do bit-by-bit addition directly.
- It's based on comparing the signs of the augend and addend:
  - If they have the same sign, add the magnitudes and keep that sign.
  - If they have different signs, then subtract the smaller magnitude from the larger one. The sign of the number with the larger magnitude is the sign of the result.
- This method of subtraction would lead to a rather complex circuit.
  - A decimal example

$$\begin{array}{r} + 3 \quad 7 \quad 9 \\ + -6 \quad 4 \quad 7 \\ \hline -2 \quad 6 \quad 8 \end{array}$$

because

$$\begin{array}{r} 5 \quad 13 \quad 17 \\ 6 \quad 4 \quad 7 \\ - 3 \quad 7 \quad 9 \\ \hline 2 \quad 6 \quad 8 \end{array}$$

# One's complement representation

- A different approach, **one's complement**, negates numbers by complementing each bit of the number.
- We keep the sign bits: 0 for positive numbers, and 1 for negative. The sign bit is complemented along with the rest of the bits.
- Examples:

$$\begin{array}{ll} 1101_2 = 13_{10} & \text{(a 4-bit unsigned number)} \\ 01101 = +13_{10} & \text{(a positive number in 5-bit one's complement)} \\ 10010 = -13_{10} & \text{(a negative number in 5-bit one's complement)} \end{array}$$

$$\begin{array}{ll} 0100_2 = 4_{10} & \text{(a 4-bit unsigned number)} \\ 00100 = +4_{10} & \text{(a positive number in 5-bit one's complement)} \\ 1011 = -4_{10} & \text{(a negative number in 5-bit one's complement)} \end{array}$$

# Arithmetic with one's complement

## ■ To add one's complement numbers:

- First do unsigned addition on the numbers, including the sign bits.
- Then take the carry out and add it to the sum.

## ■ Examples:

$$\begin{array}{r} 0111 \quad (+7) \\ + 1011 \quad + (-4) \\ \hline 1 \ 0010 \\ \\ 0010 \\ + \quad 1 \\ \hline 0011 \quad (+3) \end{array}$$

$$\begin{array}{r} 0011 \quad (+3) \\ + 0010 \quad + (+2) \\ \hline 0 \ 0101 \\ \\ 0101 \\ + \quad 0 \\ \hline 0101 \quad (+5) \end{array}$$

## ■ This is simpler and more uniform than signed magnitude addition. Drawbacks of one's complement:

- Two representations of 0: 00000000 (+0) and 11111111 (-0)
- Need to take care of the carry for addition.

# Two's complement representation

- Our final idea is two's complement. To negate a number, complement each bit (just as for ones' complement) and then add 1.
  - Or, from LSB to MSB, don't negate any bit upto-and-including the least significant '1' bit, and then negate the rest.

- Examples:

$1101_2 = 13_{10}$  (a 4-bit unsigned number)  
 $01101 = +13_{10}$  (a positive number in 5-bit two's complement)  
 $10010 = -13_{10}$  (a negative number in 5-bit *ones'* complement)  
 $10011 = -13_{10}$  (a negative number in 5-bit two's complement)

$0100_2 = 4_{10}$  (a 4-bit unsigned number)  
 $00100 = +4_{10}$  (a positive number in 5-bit two's complement)  
 $11011 = -4_{10}$  (a negative number in 5-bit *ones'* complement)  
 $11100 = -4_{10}$  (a negative number in 5-bit two's complement)

# Arithmetic with two's complement

- Negating a two's complement number takes a bit of work, but addition is much easier than with the other two systems.
- To find  $A + B$ , you just have to:
  - Do unsigned addition on  $A$  and  $B$ , including their sign bits.
  - Ignore any carry out.
- For example, to find  $0111 + 1100$ , or  $(+7) + (-4)$ :
  - First add  $0111 + 1100$  as unsigned numbers:

$$\begin{array}{r} 0111 \\ + 1100 \\ \hline 10011 \end{array}$$

- Discard the carry out (1).
- The answer is  $0011$  (+3).

# Why does it work?

- For  $n$ -bit numbers, the negation of  $B$  in two's complement is  $2^n - B$  (this is one of the alternative ways of negating a two's-complement number).

$$\begin{aligned} A - B &= A + (-B) \\ &= A + (2^n - B) \\ &= (A - B) + 2^n \end{aligned}$$

- If  $A \geq B$ , then  $(A - B)$  is a positive number, and  $2^n$  represents a carry out of 1. Discarding this carry out is equivalent to subtracting  $2^n$ , which leaves us with the desired result  $(A - B)$ .
- If  $A < B$ , then  $(A - B)$  is a negative number and we have  $2^n - (B - A)$ . This corresponds to the desired result in two's complement form.

# Overflow and underflow of signed integer

---

## ■ **Overflow** (signed integer)

- The value is bigger than the largest integer that can be represented

## ■ **Underflow** (signed integer)

- The value is smaller than the smallest integer that can be represented

# Exercises

---

■ **Convert decimal number to 2's complement number on 6 bits**

■ Q1.  $(19)_{10} = (?)_2$

■ Q2.  $(-32)_{10} = (?)_2$

■ Q3.  $(32)_{10} = (?)_2$
